1. PROPERTIES OF RINGS

1.1. Ring Homomorphisms.

Definition 1.1.1. If R and S are rings, a function $\phi : R \rightarrow S$ is called a *ring homomorphism* provided that

- (a) ϕ is a homomorphism of *additive groups*,
- (b) ϕ preserves multiplication; i.e. for all $x, y \in R$ we have $\phi(xy) = \phi(x)\phi(y)$, and
- (c) $\phi(1_R) = 1_S$.

Definition 1.1.2. The *kernel* of the ring homomorphism $\phi : R \rightarrow S$ is given by

$$\ker \phi = \phi^{-1}(0) = \{x \in R \mid \phi(x) = 0\};$$

thus $\ker \phi$ is just the kernel of ϕ viewed as a homomorphism of additive groups.

Here are some properties of the kernel:

- (K1) $\ker \phi$ is an additive subgroup of R
- (K2) for every $r \in R$ and every $x \in \ker \phi$ we have $rx \in \ker \phi$.

1.2. Ideals of a ring. For simplicity suppose that the ring R (and S) are *commutative* rings.

Definition 1.2.1. A subset I of R is an *ideal* provided that

- (a) I is an additive subgroup of R , and
- (b) for every $r \in R$ and every $x \in I$ we have $rx \in I$.

We sometimes describe condition (b) by saying that " I is closed under multiplication by every element of R ".

The proof of the following is immediate from definitions:

Proposition 1.2.2. *If $\phi : R \rightarrow S$ is a ring homomorphism, then $\ker \phi$ is an ideal of R .*

1.3. Quotient rings. Let R be a commutative ring and let I be an ideal of R .

Since I is a subgroup of the (abelian) additive group R , we may consider the quotient group R/I . Its elements are (additive) cosets $a + I$ for $a \in R$.

It follows from the definition of cosets that the $a + I = b + I$ if and only if $b - a \in I$.

The additive group can be made into a commutative ring by defining the multiplication as follows:

For $a + I, b + I \in R/I$ (so that $a, b \in R$), the product is given by

$$(a + I)(b + I) = ab + I.$$

In order to make this definition, one must confirm that this rule is well-defined. Namely, if we have equalities $a + I = a' + I$ and $b + I = b' + I$, we need to know that

$$(a + I)(b + I) = (a' + I)(b' + I).$$

Applying the definition, we see that we must confirm that

$$ab + I = a'b' + I.$$

For this, we need to argue that $a'b' - ab \in I$.

Since $a + I = a' + I$, we know that $a' - a = x \in I$ and since $b + I = b' + I$ we know that $b' - b = y \in I$.

Thus $a' = a + x$ and $b' = b + y$. Now we see that

$$a'b' = (a + x)(b + y) = ab + ay + xb + xy$$

Since I is an ideal, we see that $ay, xb, xy \in I$ hence $ay + xb + xy \in I$. Now conclude that $a'b' + I = ab + I$ as required.

It is now straightforward to confirm that the ring axioms hold for the set R/I with these operations.

Proposition 1.3.1. *If I is an ideal of the commutative ring R , then R/I is a commutative ring with the addition and multiplication just described.*

1.4. Principal ideals.

Definition 1.4.1. If R is a commutative ring and $a \in R$, the *principal ideal generated by a* – written Ra or $\langle a \rangle$ – is defined by

$$Ra = \langle a \rangle = \{ra \mid r \in R\}.$$

Proposition 1.4.2. *For $a \in R$, Ra is an ideal of R .*

Example 1.4.3. Let $n \in \mathbb{Z}_{>0}$ and consider the principal ideal $n\mathbb{Z}$ of the ring \mathbb{Z} generated by $n \in \mathbb{Z}$.

As an additive group, $n\mathbb{Z}$ is the infinite cyclic group generated by n .

The quotient ring $\mathbb{Z}/n\mathbb{Z}$ is the finite commutative ring with n elements; these elements are precisely the *congruence classes* of integers modulo n .

1.5. Isomorphism Theorem.

Theorem 1.5.1. *Let R, S be commutative rings with identity and let $\phi : R \rightarrow S$ be a ring homomorphism. Assume that ϕ is surjective (i.e. onto). Then ϕ determines an isomorphism $\bar{\phi} : R/I \rightarrow S$ where $I = \ker \phi$, where $\bar{\phi}$ is determined by the rule*

$$\bar{\phi}(a + I) = \phi(a) \quad \text{for } a \in R.$$

Proof. First, you must confirm that $\bar{\phi}$ is *well-defined*; i.e. that if $a + I = a' + I$ then $\bar{\phi}(a + I) = \bar{\phi}(a' + I)$.

Next, you must confirm that $\bar{\phi}$ is a ring homomorphism (this is immediate from the definition of ring operations on R/I).

Finally, you must confirm that $\ker \bar{\phi} = \{0\}$, where here 0 refers to the additive identity of the quotient ring R/I . This additive identity is of course the trivial coset $I = 0 + I \in R/I$. \square

1.6. A Homomorphism from the polynomial ring to the scalars. Let F is a field and let $a \in F$. consider the mapping

$$\Phi : F[T] \rightarrow F$$

given by $\Phi(f(T)) = f(a)$. Namely, applying Φ to a polynomial $f(T)$ results in the value $f(a)$ of $f(T)$ at a .

The definition of multiplication in $F[T]$ guarantees that Φ is a ring homomorphism.
